Research Background

GLMN is a phosphorylated protein that is a member of a Skp1-Cullin-F-box-like complex. The protein is essential for normal development of the vasculature and mutations in this gene have been associated with glomovenous malformations, also called glomangiomas. Alternatively spliced variants that encode different protein isoforms have been described but the full length nature of only one has been determined. GLMN may represent a naturally occurring ligand of the immunophilins FKBP59 and FKBP12 and may function as an membrane anchoring protein. Isoform 1 may stimulate the p70S6K pathway. Isoform 2 may inhibit cell proliferation and increase IL2 production.
